

AgenticCore Forex Premium Tier 1

Next-generation research framework - complete capabilities, current status, and remaining work

Executive status

This report is a current-state project record prepared from the Replit source tree, existing specifications, test results, and the latest code. It separates features that are implemented in code from features that are planned, partially validated, or still require a controlled VPS environment.

Prepared: 25 August 2026 (Asia/Dubai)

Source of truth for code: Replit workspace

VPS status: only what was visible from the submitted Windows terminal output is treated as verified

Important: this is a software and deployment status report, not a promise of trading profits. Live execution remains subject to market conditions.

AgenticCore Forex Premium Tier 1

1. Project purpose and boundary

CURRENT POSITION - Premium Tier 1 is the next-generation, research-driven Forex framework built on the Tier 2 foundation. It is intentionally separate from the stable Tier 2 runtime and is not a replacement that should be rushed into live trading.

The chosen initial broker is JustMarkets. The primary style is intraday multi-trade, with Gold as a core specialist asset, Silver as a related specialist, and Oil restricted to rare event-driven opportunities. The target of approximately 30% better accuracy/management is a measurement objective, not a guaranteed result.

The design keeps research, replay, paper, demo, and live execution isolated. Deterministic risk and execution controls must remain stronger than any AI recommendation.

2. Features and capabilities built in the current Premium slice

Project structure and safe modes

- Separate premium package with config, domain, MT5 adapters, analysis, risk, storage, runtime, logs, tests, and entry point.
- Default mock + signal-only behavior; no trades can be placed by default.
- Supported progression is mock, signal, demo data signal-only, and a future demo/auto phase.
- Unique Premium magic number and separate state namespace are defined.
- Environment-driven configuration keeps credentials out of code and version control.

Broker and runtime foundation

- MT5 bridge, mock bridge, and factory abstraction are present.
- Explicit broker/account expectations and symbol suffix settings are supported by configuration.
- Runtime manager orchestrates scans, writes atomic state, and appends audit records.
- Session baseline storage and restart-safe state writing are present.
- JustMarkets-first settings support terminal path, server, broker identity, account type, and suffix.

Analysis and signal quality

- Multi-timeframe indicator pipeline is present.
- Completed-candle VolumeSense classifies volume as LOW, NORMAL, or HIGH using a trailing median.
- Forex low-volume gating and separate metals volume policy are supported.
- ConfidenceCalibrator uses a bounded four-component score: base technical 40, timeframe agreement 25, volume participation 20, context quality 15.
- Risk/entry guards check kill switch, data age, spread, entry window, session baseline, daily P&L, pair/currency/correlation exposure, confidence, and volume.
- Signal-only manager tests cover real orchestration behavior with safe mock data.

Account/session/risk foundation

- Dubai timezone is the intended operating timezone.
- Entry window is 05:00 through 23:29 Dubai time.
- Session baseline is intended to survive restart and fail closed when unavailable.
- Default policy is a 15% daily loss lock and 20% daily profit lock based on the live session baseline.
- Maximum positions, per-pair positions, currency exposure, correlated positions, spread, data age, and minimum confidence are configurable.
- Metals can use different volume gating from currency pairs.
- Independent confirmation is fail-closed for future scale-in behavior.

Audit and current validation

exhaustion, or controlled trailing.

- Idempotent live order requests and broker-result reconciliation after every action still need production implementation.
- Slippage, liquidity, abnormal tick, and full contract validation still need completion.
- Demo execution is intentionally unavailable in the current slice.

Market data and event intelligence

- No economic-calendar provider is integrated.
- No high-impact event blackout or post-event stabilization logic is complete.
- No production financial-news/geopolitical provider is integrated.
- No cross-asset context layer for DXY, yields, oil, volatility, or currency strength is complete.
- No second market-data provider for anomaly/spread comparison is complete.
- Provider timestamps, freshness, caching, retry, rate-limit, licensing, and normalized entities need a full adapter layer.

Specialists and strategy

- Gold specialist module is not yet complete, even though Gold is a core product decision.
- Gold contract, tick value, spread, hours, volatility, USD/yields/news context, and separate backtesting still need to be implemented.
- Silver specialist rules and contract validation remain.
- Oil remains disabled by default and still needs event qualification, multi-source confirmation, a separate risk budget, and positive-expectancy evidence.
- Regime classification for trend/range/volatility/transition remains.
- Liquidity sweeps, divergence, volatility spikes, spread shocks, reversal, thesis invalidation, pair/session/regime thresholds, and meta-labeling remain.
- Confidence must ultimately be calibrated from realized outcomes rather than fixed bonuses alone.

Memory, research, and AI copilot

- Full candidate and executed-trade memory is not complete.
- The future store must retain feature snapshots, thesis, regime, session, spread, news, MFE, MAE, and exit reason.
- Loss classification and accepted-versus-rejected opportunity analysis remain.
- Pair/session/regime reports, historical replay, walk-forward testing, out-of-sample testing, Monte Carlo, and stress testing remain.
- Telegram execution control, heartbeat alerts, disconnect alerts, stale-data alerts, pause alerts, and risk-change confirmation remain.
- OpenAI copilot tools and permissions still need to be implemented with an allow-list and explicit confirmation for high-impact changes.
- LLMs must remain advisory and must never bypass deterministic risk or expose credentials.

4. Current status

CURRENT POSITION - Premium Tier 1 is a working safe foundation and signal-only/mock

prototype, not a live trading product. The current implementation proves the architecture, data-quality/risk guard concepts, state/audit behavior, and safe orchestration. It has not passed the research, demo, execution, or deployment phases required before live use.

The Premium project is therefore not stuck; it is at the correct early stage for a new trading system. It should not be enabled in auto mode until the missing sizing, SL/TP, position management, provider, and validation layers are complete.

5. Remaining roadmap

Phase 0 - Freeze and baseline

- Add timestamps, freshness, retries, caching, rate limits, and licensing checks.

Phase 3 - Gold and Silver

- Build and separately test Gold and Silver specialists.
- Validate JustMarkets contracts, spread, volatility, hours, and position size.

Phase 4 - Core strategy

- Add regime, structure, reversal, invalidation, calibrated confidence, bounded dynamic SL/TP, and controlled scale-in policy.

Phase 5 - Oil event module

- Keep disabled by default.
- Add OPEC/inventory/supply/geopolitical event qualification, multi-source confirmation, longer-horizon management, and separate risk budget.

Phase 6 - Memory and copilot

- Record all candidates and trades, classify outcomes, build reports, and add a restricted explanatory/research copilot.

Phase 7 - Validation and Phase 8 - Deployment

- Historical replay with realistic spread, commission, slippage, walk-forward, out-of-sample, Monte Carlo, stress, signal-only, paper/demo, and comparison against Tier 2.
- Deploy one isolated JustMarkets demo worker only after validation, verify Telegram/account identity, observe, and expand accounts only through isolated workers.

6. Bottom line

CURRENT POSITION - Premium Tier 1 has a tested foundation and a clear architecture, but most of the research-grade strategy, external data, execution, memory, and validation work is still ahead. The correct next step is to finish the controlled Tier 2 operational validation, then use Tier 2 as the frozen baseline while building Premium in isolated phases.
